LIFE AFTER DEATH: THE SCALE AND SALIENCE OF MORTALITY EXPOSURE IN SUB-SAHARAN AFRICA

Dramatic reductions in the infant and under-five mortality rates over the last half century are among the global health community's most notable achievements. The trends are clear and the message is positive: the world today is healthier and safer for young people than it has ever been. Sub-Saharan African countries, in particular, have experienced some of the most dramatic reductions in early life mortality. However, the all-time low infant and under-five mortality rates conceal the pervasiveness by which contemporary populations experience the phenomenon of having an infant or under-five-year-old child die—a life event that can leave parents vulnerable in myriad ways.
